Title : Effect of β -Radiators on Development and Phys-
iological Activity of Azotobacter.

Orig Pub: Mikrobiologiya, 1957, 26, No 5, 519-535.

Abstract: The effect of a mixture of β -radiators (fragments of uranium-235 fission) on Azotobacter development was studied. The radiators were introduced into nutritive media in concentrations of 0.1-160 millicurie/liter. Upon introduction of small quantities of radiators into nutritive media, a temporary stimulation of bacterial develop-

Abstract: ment is noted. Individual processes taking place in the cells display different sensitivity to the action of radiators. The most sensitive is cell division, and the most stable are energy processes and fixation of atmospheric nitrogen. Although fixation of atmospheric nitrogen is a very stable process, incorporation of fixed nitrogen into protein becomes disturbed at comparatively low concentrations of radiators, and in media and cultures there is a change of the relation of protein and non-protein nitrogen towards the increase of the nonprotein part. Under cultivation in media with radiators, the Azotobacter cells strongly concentrate the radio-

1099. COMPARATIVE STUDY OF THE EFFECT OF ALPHA AND BETA RADIATIONS ON MICROORGANISMS (Russian text) - Sokurova E. N. - BIOFLIZKA 1958, 3/4 (474-478) Graphs 3 Tables 5

In accordance with data already cited in the literature, the results of these experiments demonstrated that α -radiations, giving a high linear ionization density, inhibit the development of bacteria considerably stronger than β -radiations. Po^{210} , introduced into a nutritive medium in concentrations equivalent in their dose to stimulating concentrations of β -radiations, sharply inhibits the development of nitrobacteria and of azotobacteria. Mixed α - and β -radioactive substances (radium) in the medium in concentrations equivalent to α - and β -radiations produce an intermediate effect. After an initial inhibition of development radium may give a stimulating effect. The energetic processes in microorganisms and their processes of atmospheric nitrogen fixation are also more sensitive to the effect of α - than of β -radioactive substances.

TITLE: X-Ray Induced Hereditarily Modified Forms of Yeast Organisms Producing Increased Amounts of Ergosterin (Vozniknoveniye pod vliyaniyem rentgenovskikh luchey nasledstvenno izmenennykh form drozhzhevykh organizmov, obrazuyushchikh povyshennoye kolichestvo ergosterina)

PERIODICAL: Doklady Akademii Nauk SSSR, 1958, Vol 119, Nr 2, pp 265 - 266 (USSR)

ABSTRACT: In the irradiation of yeast organisms with great dosages of X-rays and in their subsequent cultivation on nutrients a considerable amount of ergosterin accumulates in them. Such cultures contain 2-3 times as much ergosterin as non irradiated cultures. In connection herewith it is of interest to investigate if considerably modified yeast organisms (producing an increased amount of ergosterin) can form on the action of this irradiation. For the investigation a culture of *Saccharomyces carlsbergensis* Frohberg with a normally rather high ergosterin content was selected. The irradiation was carried out in aqueous solutions by means of the X-ray appa-

X-Ray Induced Hereditarily Modified Forms of Yeast Organisms Producing
Increased Amounts of Ergosterin

content. In long lasting cultivation without repeated irradiation the high content of ergosterin in the irradiated races slowly decreases. Thus the hereditary feature of this characteristic is not very marked. An occurrence of yeast races with increased ergosterin content is also possible in the case of irradiation with ultraviolet light. The irradiated yeast races with increased ergosterin content do not essentially differ in their radiation sensitivity from the original forms, although indications exist of a possible protective action of ergosterin against radiation dependent injuries. TITLE: Deformation Systems of α -Zirconium (Sistemy deformatsii α -tsirkoniya)

PERIODICALS: Atomnaya Energiya, 1958, Vol. 4, Nr 5,
pp. 443 - 447 (USSR)

ABSTRACT: The deformation systems of α -zirconic iodide were investigated in large-grained (average diameter 0.5 - 1.5 mm), semi-crystalline (5 x 5 x 7 mm) samples that had been deformed by annealing. The orientation of the grains was determined by a Laue diagram. This was taken by a special reflex camera with the light ray having particularly small dimensions. The indices of the deformation systems were determined by means of the double-plate method or of the method of geometrical localization of the poles.
It was stated that α -zirconium is deformed by slip in the plane (1010) in direction [1210] and in the plane (1011). A series of twinning-systems was determined in α -zirconium:
a) $K_1(10\bar{1}2), \eta_1 [10\bar{1}1], K_2(10\bar{1}2), \eta_2 [10\bar{1}1]$, $s = 0,173$

TITLE: The influence of the Structure and Properties of Uranium on its Behaviour Under Irradiation (Vliyanie strukturny i svoystv urana na ego povedeniye pod oblucheniym)

PERIODICAL: Atomnaya energiya, 1958, Vol 5, Nr 4, pp 412-420 (UDC R)

ABSTRACT: It was possible to show that by varying the composition of the alloys and by changing the thermal treatment the consequences of the modification of the size of grain of the nucleus and the texture of uranium after irradiation can partly be eliminated. The dependence of the size of the nuclear grain of the enriched uranium, its hardness, its strength limit, and its stretching-strain limit upon the iron-, silicon-, and aluminum content in the alloy is determined by experiment. The cooling-down rate and the content of the admixtures mentioned influence the position of the β - α transformation point. At a cooling-down rate of 400°C/sec and a silicon content of 0.05 weight percents the transformation point between the β - and the α -phase decreases to 550°C. Experiments proved a 50- to 100-fold acceleration of

Part 2

NOV 69-5-4-3/24

The Influence of the Structure and Properties of Uranium on Its Behavior
Under Irradiation

Creep under irradiation ($\nu = 3 \cdot 10^{12} \text{ n/cm}^2 \cdot \text{sec}$) for textured uranium as well as for uranium with a disorientated structure. The creep-rate of disorientated uranium is closely connected with the velocity of stand-by losses. The mechanical properties of uranium, especially dilatation in the reactor, were investigated experimentally. Even after a short stay of the uranium in the reactor (less than 1 hour) the relative modification of the length becomes less and the strength limit increases. The experimentally found values of G are considerably higher than those given in reference 3. A. G. Lanin, V. M. Popilinskaya, V. K. Zakharova, L. A. Protsenko, V. N. Golevanova, and F. A. Borisev took part in the investigations. There are 10 figures, 1 table, and 12 references, 1 of which is Soviet.

PREFACT: This volume is intended for scientists, engineers, technicians, and
technologists working in the production and peaceful application of atomic
technology; for entrepreneurs and administrators of atomic or nuclear
industries; for educational institutions where the subjects is taught; and for people
interested in atomic science and technology.

CONTENTS: This is volume 3 of a 2-volume set of reports on atomic energy, presented
by Soviet scientists at the Second International Conference on the
Peaceful Uses of Atomic Energy, held in Geneva from September 1 to 15, 1958.
Volume 3 consists of two parts. The first part, edited by A.I. Zubov is
devoted to general, prospecting, and processing of nuclear materials and
nuclear material. The second part, edited by G.I. Zverev, contains 70 reports
on metallurgy, proton-beam irradiation effects on metals, the titles of which
mention metals, and neutron irradiation effects on metals. The titles of the
individual papers in most cases correspond word for word with those in the
official English language edition of the Conference proceedings. See
May 2/2001 for the titles of the other volumes of the set.

TITLE:

The Influence of Radiation Upon Solids (Vliyaniye obлучeniya na tverdyye tela)

PERIODICAL: Atomnaya energiya, 1959, Vol 6, Nr 4, pp 403-425 (USSR)

ABSTRACT:

On the basis of the Geneva reports of 1958 listed below this review has been compiled and deals with the subject mentioned in the title. As far as the quantitative damage done to irradiated material can be experimentally determined, it is recorded by tables like the damage caused by neutron irradiation in uranium, plutonium, and some of their alloys. Also the influence exercised by a high degree of burn-up (up to 2 atomic%) upon the shape of the individual parts made from uranium and its alloys as well as the increase of volume connected therewith is taken into account. The data concerning uranium-molybdenum alloys (9% by weight) and pure uranium are given separately. These data show the extent of the influence exercised by irradiation upon atomic mobility in uranium and its alloys. The abstract contains also data concerning the influence exercised by temperature and the radiated dose upon the mechanical properties of the various types

Card 1/2

The Influence of Radiation Upon Solids

SOV/80-5-4-4/27

of steel and other building materials. Furthermore, data concerning the influence exercised by irradiation upon non-metallic materials such as BeO, UO₂-ReO₂, UO₂-ThO₂, graphite, etc., are given. The following reports were used for the compilation of information: 29, 50, 80, 190, 612, 614, 617, 618, 621, 622, 679, 713, 998, 1158, 1159, 1452, 1785, 1805, 1855, 1866, 1878, 1890, 1978, 2052, 2129, 2192, 2385, 2405. TITLE: Investigation of the Increase in Internal Friction in Samples
of Polycrystalline Uranium With Temperature Variation

PERIODICAL: Atomnaya energiya, 1960, Vol. 8, No. 4, pp. 348-353

TEXT: Samples of polycrystalline uranium of varying composition were investigated which had been hardened from the gamma phase, annealed in the gamma phase and such which had been recrystallized. The experiments were made in three temperature intervals from 20 to 290°C. In this connection the dependence of the increase in internal friction on the heating rate and the various structural states was observed. The rapidity with which internal friction increases is gradually reduced and attains a value which is approximately proportional to the heating rate of the sample. The increase in internal friction is related with the strain which is produced in the sample with temperature variation due to the anisotropy of the coefficient of thermal expansion. At temperatures exceeding 350°C the effect of the increase in internal friction is

TITLE: Increase of Internal Friction in Uranium on a Change of
Its Temperature ✓

PERIODICAL: Atomnaya energiya, 1960, Vol. 9, No. 5, pp. 392 - 398

4
4

TEXT: The present paper follows a previous one in which it was established that the internal friction of uranium increases rapidly on heating. This increase in internal friction is attributed to microstresses and deformations of the polycrystalline grains of the sample due to anisotropic change of form of the crystals on change of temperature. A theoretical and an experimental part of the present paper give a semiquantitative estimate of the dependence of the increase of internal friction on the rate of heating, the frequency, and the amplitude of pendulum oscillations. First, the temperature-dependent change of deformation ε and stress σ in a grain of a uranium (average coefficient of linear expansion $\alpha_m \approx 17.3 \cdot 10^{-6}$) is theoretically studied and some

formulas are derived. The theoretical dependence of the increase of internal friction on heating from 20° to 120°C on the quantity $v\tau$ (v - rate of heating, τ - period of oscillation) is compared with the experimental values in Fig.3. The apparatus used for the experiment, and the method of preparation of the samples were the same as described in Ref.1; the method was changed in unimportant details. The results of the experiments are discussed in detail. It is found that the increase of internal friction as a function of the heating time for different values of τ and $v \leq 50^{\circ}\text{C}/\text{min}$ is similar to the previously obtained result for $\tau = 0.5$ sec and $v \leq 20^{\circ}\text{C}/\text{min}$. The details of the dependence are shown in Fig.3. There were great difficulties involved in the determination of the amplitude dependence. Fig.4 shows the change Δ of internal friction as a function of A_{\max} . It was experimentally found that

$\Delta = 7.2 \cdot 10^{-3} + 3.5 \cdot 10^{-8} / A_{\max}$. The effect of the initial state of the sample on the increase of internal friction was studied, and is shown in several diagrams. It is found that on a change of temperature the relaxation processes in polycrystalline uranium are intensified and lead to an increase of internal friction. The increase of internal

friction depends mainly on $v\tau$. For small values of $k\tau/A$, it is proportional to $v\tau$; for large values, however, saturation is reached. The theoretical estimates are in good agreement with the experimental data. There are 6 figures, 1 table, and 3 Soviet references.

AUTHOR: Konobeyevskiy, S. T.; Levitsky, B. M.; Sokurskiy, Yu. N.; Andreyev, G. A.

TITLE: The possibilities and prospects of hardening metals and alloys by irradiation

SOURCE: Soveshchaniye po uprochneniyu detaley mashin, 1962. Protsessy uprochneniya detaley mashin (Processes of the hardening of machine parts); doklady soveshchaniya. Moscow, Izd-vo Nauka, 1964, 104-108

TOPIC TAGS: metal irradiation, alloy irradiation, gamma irradiation, beta irradiation, neutron bombardment, metal hardening, metal surface hardening, radiation hardening

ABSTRACT: It is well known that irradiation may cause not only a deterioration of metal properties, but also their improvement. Thus, radiation sharply increases the yield point and moderately increases the ultimate strength and wear resistance. Hardening under irradiation is accompanied by lowering of plasticity. Different types of radiation, however, act differently on the atoms of the irradiated material. When the primary particles interact with the atoms of metals, energy is transmitted to the metal atoms. When this energy exceeds about 25-35 electronvolts, the atom is displaced from the lattice, and the energy of the first displaced atom may be sufficient for the displacement

Card 1/3

L 40004-65

ACCESSION NR: AT4049819

of other atoms. Thus, clusters of displaced atoms are formed. This displacement affects the properties of alloys considerably. The number of secondary displaced atoms depends on the energy of the primary displaced atom. Under neutron bombardment, when the energy of the primary displaced atoms is great, this number may be several hundred, while gamma and beta irradiation only produces 1 to 2. Point defects arise under irradiation, changing the properties of the metals (increasing electrical resistance, lowering internal friction, increasing the modulus of elasticity, etc.). Dislocations are formed by irradiation, resulting in hardening, which can in some cases be increased by additional irradiation. The future of radiation hardening lies in a combination of irradiation with subsequent heat treatment, irradiation being the initiating factor. It should be noted that new elements are created by irradiation with different properties. At the present stage of development of nucleonics, the cost of irradiation in an atomic pile is too high for neutron bombardment to be used for increasing the strength of large sets of parts. Even though gamma irradiation is weaker, the same results are obtained and it may be used in the future since the material does not become radioactive. Electron irradiation produces changes in structure in the same way as gamma irradiation, but only in the surface layer, causing surface hardening by heating. Heavy ions are also being

Card 2/3

L 40004-65

ACCESSION NR: AT4049819

used for irradiation, resulting in even better hardening of materials. The layers arising under irradiation differ from diffusion layers and may be irregular, but the stability may be increased and the bond with the base metal is better; only the first steps have been made in this direction. The role of thermal equilibriums during the fusion and granulation of metallurgical slags. S. Sotacolu and D. Totocu (Polytech. Inst., Bucharest, Romania). Acced. rep. populară Române, Bul. științ. Sect. științ. teh. și chim. 5, 99-120 (1953). — The hydraulic values (moduli) of the granulated slags in the system CaO-MgO-Al₂O₃-SiO₂ were investigated, and discontinuous changes were found, with max. and min., as a function of the Al₂O₃, of the CaO, and of the MgO assays. The thermal equil. parageneses were investigated in this system, and a correlation was found between the type of the paragenesis of the slags and the hydraulic properties of same. The irregularity in the hydraulic resistances was not only a function of the oxide compn. of the slags, but also a function of the type of paragenesis. In this way the role of the thermal equil. upon fusion and granulation of the metallurgical slags were elucidated. It was thus concluded that the hydraulic properties of the slags depended upon the type of paragenesis, the heterogeneous phase compn. detd. the hydraulic values. The parageneses were actually made up of 19 different minerals, which could be classified as melilitic, Akermanite-anortitic, those with over 25% Al₂O₃, and those with free MgO. 20 references. Electronic differential thermobalance. Serban Schaeffel, Petru Baltu, and Radu Dimescu (Inst. Politehnica, Bucharest, Romania). *Bul. inst. politehnica Bucuresti* 19, 199-204 (1957) (Russian and French summaries).—An ordinary analytical balance with a sensitivity of 0.1 mg. was used. The equil. position is detected by a capacitor mounted on one of the arms of the balance; the capacitance depends on the position of the arm and it is relayed electronically. The equil. is restored by an electromagnetic system attached to the other arm of the balance. The potentiometric memorization system for the differential loss in wt. is part of the electromagnetic restoring system. A millivoltmeter recorder with a triple switch is used to record either the temp., the normal loss in wt., or the differential loss in wt. The elec. furnace with a program regulator for 100-200°/hr. can be heated up to 1600° and it is located just below one arm of the balance. The precision of the balance, which is of the order of 0.1%, corresponds to the sensitivity.

AUTHOR: Solacolu, Serban

TITLE: Influence of the Liquid Phase on Properties of Magnesite Refractories

PERIODICAL: Silikattechnik, 1961, No. 1, pp. 17-21

TEXT: The physical properties of magnesite refractories depend on their composition, the amount of liquid phase formed at higher temperature, and on the mineralizing process of solid phases in a state of equilibrium, especially the periclase. The position of magnesite-, dolomite-magnesite-, spinel-magnesite-, and forsterite-magnesite refractories in the multi-component system $MgO - MgO.Al_2O_3 - MgO.Fe_2O_3 - 2MgO.SiO_2 - 2CaO.SiO_2$ was determined by the author in a previous paper (Ref. 1). For the determination of the liquid-phase influence on the firing properties (shrinkage, porosity), these refractories were synthesized, the amount of liquid phase at 1550°C was calculated from the thermal equilibrium and recorded in a diagram in dependence on composition expressed in modules. Further diagrams

show shrinkage during firing and porosity as a function of composition. A direct proportionality between firing properties and the content of liquid phase was established; a summary diagram shows that shrinkage during firing increases and porosity decreases with increasing content of liquid phase. As the second component, the mineralizing process of the periclase determining the firing properties, was kept constant through the constant periclase content in the author's experimental series, it could be excluded from consideration. The present studies show that when selecting manufacturing formulas, the amount and composition of the liquid phase, besides the raw material composition, must be considered, since there are several products which at different initial composition show equal properties due to the equality of their liquid phase. There are 6 figures, 2 tables, and 1 non-Soviet reference.

Production of magnesia based on...

obtain MgO powder, then in a rotating furnace, together with a mineralizer, until clinkering occurs. Ilmenite, bauxite, siderite, or ankerite are used as mineralizers. Chromo-magnesite and magnesite-chromite refractories are prepared, with a ratio 1:1 of rough and fine fractions. With increasing chromite content, the water absorption and heat resistance of the goods are increased. It was found that complete or partial substitution of chromite by bauxite makes it possible to obtain magnesite-spinel refractory materials; the baking temperature for chromo-magnesite goods is 1710°C and for magnesite goods 1620°C. TITLE: The synthesis and uses of some molecular sieves. II. The synthesis of some
granular molecular sieves from kaolin

SOURCE: Revista de Chimie, v. 15, No. 7, 1964, 404-408

TOPIC TAGS: molecular sieve, kaolin, kaolin sieve preparation, kaolin
granulation, Malaxa process, kaolin extrusion, calcination

ABSTRACT: The authors report the results of experiments carried out with the intention
of reproducing the synthesis of molecular sieves from kaolin, without the addition of bind-
ing agents and using methods which vary slightly from those previously described in the
literature. The kaolin found in Aghires, Rumania, was used as the basic material; either
the 1st (78% kaolin) or 2nd (75% kaolin) grade of this material may be used, both being able
to yield sieves with high absorption capacities (25-32g H₂O/100g) with pores of 4A. The
static absorption capacities were first determined for both types of material; the results
are reported in tables, and a schematic diagram of the laboratory apparatus used is also
given. The various steps used in the actual manufacturing procedure are then described

Card

1/3

L 49216-65

ACCESSION NR: AP4044191

In detail, as follows: 1) The granulation of the kaolin to the desired dimensions (length \approx diameter) may be carried out by 2 methods: method (a) is based on the extrusion of wet kaolin paste, after previous heating at 120C and addition of 30% water ("Malaxa" process), drying and grinding of the extruded material, and final sorting of the granules; b) grinding of dry kaolin cakes directly to the desired dimensions, and subsequent sorting of the granules. 2) The calcination of the granules is carried-out partially in a laboratory oven and partially in an electric oven type KYLS, of 100 liters capacity, equipped with silica rods. The optimum temperature of calcination is 670-700C (not to exceed 750C), for a duration of 5 hours. Both ovens are equipped with temperature regulators, calibrated in intervals of \pm 20C. 3) The alkali treatment phase is carried out with a 9-10% NaOH solution (not to exceed 16%), for a period of 5-10 hours. Mechanical stirring of the kaolin granules is not recommended. Consequently, the operation is carried out partially in a boiler without stirrer, and partially in a boiler equipped with a Cottrell pump system, for the reflux of the solution. During this operation, to produce a maximum absorption capacity of the molecular sieve structure, the diameter of the granules cannot exceed 2 mm. Following alkali treatment, the molecular sieves obtained are washed with water until the washing solution reaches a pH of 9-9.5. A schematic diagram of a laboratory

Card 2/3

L 49216-65

ACCESSION NR: AP4044191

scale apparatus for the alkali treatment of the kaolin granules is given. 4) The ion-exchange phase (exchange of sodium ions for calcium ions) is carried out by 2 treatments with a 25-33% CaCl_2 solution, for 4 hours at the boiling temperature and under normal pressure. These parameters are considered optimal for the production of maximum absorption capacities. Following each treatment with CaCl_2 the molecular sieves are washed with water in order to eliminate the traces of sodium ions remaining on the surface of the granules. 5) Activation of the sieves is carried out by a process of calcination for 1 hour at a temperature of 300-350°C. Prolonged calcination (4-5 hours) results in a stable absorption capacity, having a lower value (60-70% of the initial value). The molecular sieves obtained by this process have a mechanical resistance of 1-2 kg/mm², as compared with 0.1 - 0.5 kg/mm² for those manufactured outside of Rumania, with a specific area between 500 and 700 m²/g, and a real density of 1.9-2.1 g/cm³. A diagram of an industrial installation for the manufacture of the 4A molecular sieves is given. The authors conclude by stressing the importance and specificity of the method for sieves having 4A pores. Molecular sieves with 5A pores, prepared by this method, have much lower absorption capacities. Orig. art. has: 3 figures and 7 tables.

SOLACOLU-NICOLAID A.

Effect of aluminum upon the microstructure of cast iron
with flaky and with nodular graphite. Traian Dumitrescu,
with Mihai Solacolu-Nicolaïd, and Alfred Kathrein. Acad. rep.
populare Române, Studii cercetări și; 3, 417-38(1958).
The cast iron studied contained flaky and nodular graphite
and 3-4% Si. In the iron with flaky graphite, graphitization
is complete with 3-4 and >10% Al. For the iron
with nodular graphite, graphitizing action of Al has a max.
at 3%. For both alloys, Al up to 3% will increase the amt.
of ferrite (in this case α -Fe-Al-Si) and will decrease the amt.
of pearlite (in this case a mech. mixt. of ferrite with ce-
mentite alloyed to Al). This means that Fe-3Al has a
completely ferritic structure. In iron with flaky or nodular
graphite, >3 or >4% Al, resp., gives, in addn. to the α -
phase, also the ϵ -phase. In iron with up to 5-8% Al, the ϵ
phase forms with the α phase a fine, cryst. flaky aggregate,
which seems to be similar to pearlite, but has a dendritic
habitus. If the Al assay rises still higher, the ϵ phase will
lose more and more its dendritic aspect, till at highest Al
assays it looks like the ordinary complex mixt. of carbides.
Nodular graphite occurs up to 11% Al, only if the section
thickness is very low. Al exerts a neg. effect on the forma-
tion of nodular graphite, which will be more pronounced the
lower the cooling rate of the sample. The hardness in-
creases continuously with increasing Al, and for iron contg.
nodular graphite at higher Al contents the alloy is harder
than the iron contg. flaky graphite, which has the same
amt. of Al and the same structure. Werner Jacobson

June 1954
Theoretical and
Experimental Methods

V. 193. Solaja, V. The application of dimensional analysis
to static deformation (In Serbian), Annual of the Mechanical En-
gineering Faculty, Belgrade, 1953, 95-99.

The method is used to find the equation of the force necessary
to elastically deform a solid body. By applying a proposal by
V. Scheile, the equation is received in the form $F = c \cdot d^{n_1} \cdot h^{n_2} \cdot l^{n_3}$.
The values of the coefficient c and the exponents n_1 , n_2 , and n_3 are
tabulated for the various intervals of temperature and ratios of
diameter/height. The discussion of the exponents provides in-
formation on the influence of the dimensions of the body.
